

Warren: a message-driven document processing framework.

Workers consume messages from a RabbitMQ exchange and self-select which ones to process. Each worker writes its results to a cached storage layer (MongoDB and Redis), then publishes a new message describing where those results live.

Downstream workers pick that up, fetch what they need, and publish their own result locations. Adding a worker type is purely additive: no routing configuration changes, no upstream modifications.

You scale a pipeline by running more replicas of any worker type.
